Description

Currently, the returndoctypes for each skin are defined separately. These should be moved to a centralized locate so they only need to be changed once for all skins.

Note that there are several different strategies for defining the returndoctypes including:

- as hidden form fields
- using java script
- defining in a url. This strategy also has several different forms including plain html url, html encoded url and hex encoded url.

All of these need to be handled.

- Status changed from New to Rejected

One of the point of using skins is that some skins might use doctypes that others do not. We can't really centralize this and still keep that feature.
