#### Description

Currently you can opt to save your datapackage changes to either LOCAL, NETWORK, or BOTH. This means you can make changes to a package then opt to save them only to the NETWORK. This can leave your local store a version behind and I don't understand the usecase for that.

I am proposing that we *always* save changes locally (if local does not already have the latest version).

I started thinking about this because of a related bug that displayed different local and network revisions simultaneously ([#5805](#)). I think we should still try to address that bug, but I'm not exactly sure how to guarantee it will not continue to be a problem especially if we maintain distinct revision histories for local and network content. (This may qualify as yet another bug for discussion).

Does this effectively communicate that Local saving is required?
