Description

Entering contact information for people is common and time-consuming. We could substantially streamline this process using several mechanisms. In order of complexity:

1) Collect contact information about the user in the profile. When they type their last name in a eml-party surname field, pop up a window asking if they want to use their own info, and fill it in for them if they say yes.

2) When someone enters a surname in, look it up in ldap, either on each keystroke, or when they move to the next field. This may be something we want to ask metacat to do. Pop up a dialog that doesn't prevent them from continuing to enter the name, and ask if they want to use one of the ldap entries. If they say yes, format the entry in EML and fill in the values for them.

3) Keep a list of entries in memory for parties that the user has entered previously in the current package, or in all packages. When they type in a surname, pop up a dialog as in (2) with this list and ask if they mean one of the existing people. If that person is already in the document, add a reference to that person if using eml 2. Otherwise, add the person in as an eml block.
