#### Description

Currently, table attribute names are used as variable names. There are two problem with this: 1) there is no syntax restrictions on the names 2) they can be duplicate with other names in the table. The current attribute ids can't be used as names, as they are only unique within a table rather than across all data tables used in a StepGroup, and are not necessarily syntactically legitimate as variable names. The solution is probably to generate a unique id for every attribute that is a legal name in every script language.
